#### Abstract

In this paper, we prove the existence and uniqueness of local mild and classical solutions of a class of nonlinear fractional integrodifferential equations in Banach space with analytic semigroup. Gelfand-Shilov principle and fractional powers of operators are used to establish the results.

Keywords: Fractional integrodifferential equation; Fractional powers; Mild and Classical solution; Analytic semigroup.

## 1. Introduction

In this paper, we are concerned with the following fractional integrodifferential equation in a Banach space $X$ :

$$
\begin{align*}
& \frac{d^{\alpha} u(t)}{d t^{\alpha}}+A u(t)=f(t, u(t))+\int_{0}^{t} h\left(t, s, u(s), \int_{0}^{s} k(s, \tau, u(\tau)) d \tau\right) d s,  \tag{1}\\
& u(0)=u_{0}, \tag{2}
\end{align*}
$$

where $0<\alpha \leq 1, t>0$. Let $J=[0, a]$ and let $-A$ is the infinitesimal generator of an analytic semigroup $Q(t), t \geq 0$. Let $f: J \times X \rightarrow X, h: J \times J \times X \times X \rightarrow X, k: J \times J \times X \rightarrow X$ be given nonlinear operators.

This type of research has been considered in Balachandran and Chandrasekaran [1], when the equation (1) is given with conventional (Classical) derivatives, also as many works [2, 3, 4, 5] and references cited therein. Fractional derivatives have been extensively applied in many fields, for example in Probability, Viscoelasticity, Electronics, Economics, mechanics as well as Biology. In recent years, they have been an object of investigations with much increasing interest. For more details on this theory and application, we refer the monographs of Lakshmikantham et al. [6], Miler and Ross [7], Podlubny [8] and the papers of $[9,10,11,12]$.

In this paper, we generalize the results of [1,20]. The rest of this paper is organized as follows. In section 2, we give some preliminaries. In section 3, we prove our main theorem for (1) - (2).

## 2. Preliminaries

Here we assume that $-A$ is the infinitesimal generator of a bounded analytic semigroup of linear operator in a Banach space $X$. Hence for convenience, we suppose that $\|Q(t)\| \leq M$ for $t \geq 0$ and $0 \in$ $\rho(-A)$, where $\rho(-A)$ is the resolvent set of $-A$. We define the fractional power $A^{-q}$ by

$$
A^{-q}=\frac{1}{\Gamma(q)} \int_{0}^{\infty}(t)^{q-1} Q(t) d t, q>0
$$

For $0<q \leq 1, A^{q}$ is a closed linear invertible operator with domain $D\left(A^{q}\right) \supset D(A)$ is dense in $X$. The closedness of $A^{q}$ implies that $D\left(A^{q}\right)$, endowed with the graph norm of $A^{q},\|u\|_{D(A)}=\|u\|+$ $\left\|A^{q} u\right\|, u \in D\left(A^{q}\right)$, is a Banach space. Since $A^{q}$ is invertible, and its graph norm |||. \|| is equivalent to the norm $\|u\|_{q}=\left\|A^{q} u\right\|$. Thus $D\left(A^{q}\right)$ equipped with the norm $\|\cdot\|_{q}$, is a Banach space, which we denote by $X_{q}$. Take $J=[0, a]$.

Following Gelfand and Shilov [13], we define fractional integral of order $\alpha>0$ as

$$
I_{a}^{\alpha} f(t)=\frac{1}{\Gamma(\alpha)} \int_{a}^{t}(t-s)^{\alpha-1} f(s) d s
$$

also, the fractional derivative of the function $f$ of order $0<\alpha<1$ as

$$
{ }_{a} D_{t}^{\alpha} f(t)=\frac{1}{\Gamma(1-\alpha)} \frac{d}{d t} \int_{a}^{t} f(s)(t-s)^{-\alpha} d s
$$

where $f$ is an abstract continuous function on the interval $[a, b]$ and $\Gamma(\alpha)$ is the Gamma function, see [14].

Definition 1: By a solution of (1) - (2), we mean a function $u$ with values in $X$ such that:
(1) $u$ is continuous function on $J$ and $u(t) \in D(A)$,
(2) $\frac{d^{\alpha} u}{d t^{\alpha}}$ exists and continuous on $(0, a), 0<\alpha<1$, and $u$ satisfies (1) on ( $0, a$ ) and the initial condition (2).

Using Gelfand-Shilov principle [13], it is suitable to rewrite equation (1), (2) in the form
$u(t)=u_{0}+\frac{1}{\Gamma(\alpha)} \int_{0}^{t}(t-s)^{\alpha-1}\left[f(s, u(s))-A u(s)+\int_{0}^{s} h\left(s, \tau, u(\tau), \int_{0}^{\tau} k(\tau, \mu, u(\mu)) d \mu\right) d \tau\right] d s(3)$
Remark 1: Let us take in the considered problem, the inhomogeneous part is equal to an abstract continuous function $F(t)$, then from (1) - (2), we have

$$
\begin{align*}
& D_{t}^{\alpha} u(t)+A u(t)=F(t)  \tag{4}\\
& u(0)=u_{0} \tag{5}
\end{align*}
$$

According to [14, 15-19], we first apply the fractional integral on both sides of (4) and then using (5), we apply the Laplace transform on the new integral equations by considering a suitable one-sided stable probability density whose Laplace transform is given. Hence we can conclude that a solution of the problem (4) - (5) can be formally represented by

$$
\begin{equation*}
u(t)=\int_{0}^{\infty} \zeta_{\alpha}(\theta) Q\left(t^{\alpha} \theta\right) u_{0} d \theta+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta) Q\left((t-s)^{\alpha} \theta\right) F(s) d \theta d s, \tag{6}
\end{equation*}
$$

where

$$
F(t)=f(t, u(t))+\int_{0}^{t} h\left(t, s, u(s), \int_{0}^{s} k(s, \tau, u(\tau)) d \tau\right) d s
$$

and $\zeta_{\alpha}$ is a probability density function defined on $(0, \infty)$ such that its Laplace transform is given by

$$
\int_{0}^{\infty} e^{-\theta x} \zeta_{\alpha}(\theta) d \theta=\sum_{j=0}^{\infty} \frac{(-x)^{j}}{\Gamma(1+\alpha j)}, 0<\alpha \leq 1, x>0 .
$$

## 3. Existence Theorem

To prove our main result we state the following lemma:
Lemma 1: Let $-A$ be the infinitesimal generator of an analytic semigroup $Q(t)$. If $0 \in \rho(A)$ then
(a) $Q(t): X \rightarrow D\left(A^{q}\right)$ for every $t>0$ and $q \geq 0$
(b) For every $u \in D\left(A^{q}\right)$, we have $Q(t) A^{q} u=A^{q} Q(t) u$
(c) For every $t>0$ the operator $A^{q} Q(t)$ is bounded and $\left\|A^{q} Q(t)\right\| \leq M_{q} t^{-q}$.

For more details, see [21, section 2.6]
Theorem 1: Assume that
(i) $\quad-A$ is the infinitesimal generator of a bounded analytic semigroup of linear operator $Q(t), t>0$, in $X$.
(ii) For $q \geq 0$, the fractional power $A^{q}$ satisfies $\left\|A^{q} Q(t)\right\| \leq M_{q} t^{-q}$ for $t>0$, where $M_{q}$ is a real constant.
(iii) $0 \in \rho(-A)$, the resolvent set.
(iv) For an open subset D of $J \times X_{q}, f: D \rightarrow X$ satisfies the condition, if for every $(t, u) \in D$ there is a neighborhood $V \subset D$ and constants $L \geq 0,0<\vartheta \leq 1$, such that

$$
\begin{equation*}
\left\|f\left(t_{1}, u_{1}\right)-f\left(t_{2}, u_{2}\right)\right\| \leq L\left(\left|t_{1}-t_{2}\right|^{\vartheta}+\left\|u_{1}-u_{2}\right\|_{q}\right) \tag{7}
\end{equation*}
$$

for all $\left(t_{i}, u_{i}\right) \in V, i=1,2$.
(v) For an open subset E of $J \times J \times X_{q} \times X_{q}, h: E \rightarrow X$ satisfies the condition, if for every $(t, s, u, v) \in E$ there is a neighborhood $U \subset E$ and constants $L_{1} \geq 0,0<\vartheta \leq 1$, such that

$$
\begin{align*}
& \left\|h\left(t_{1}, s_{1}, u_{1}, v_{1}\right)-h\left(t_{2}, s_{2}, u_{2}, v_{2}\right)\right\| \\
& \quad \leq L_{1}\left(\left|t_{1}-t_{2}\right|^{\vartheta}+\left|s_{1}-s_{2}\right|^{\vartheta}+\left\|u_{1}-u_{2}\right\|_{q}+\left\|v_{1}-v_{2}\right\|_{q}\right) \tag{8}
\end{align*}
$$

for all $\left(t_{i}, s_{i}, u_{i}, v_{i}\right) \in U, i=1,2$.
(vi) For an open subset P of $J \times J \times X_{q}, k: P \rightarrow X$ satisfies the condition, if for every $(t, s, u) \in$ $P$ there is a neighborhood $W \subset P$ and constants $L_{2} \geq 0,0<\vartheta \leq 1$, such that

$$
\begin{equation*}
\left\|k\left(t_{1}, s_{1}, u_{1}\right)-k\left(t_{2}, s_{2}, u_{2}\right)\right\| \leq L_{2}\left(\left|t_{1}-t_{2}\right|^{\vartheta}+\left|s_{1}-s_{2}\right|^{\vartheta}+\left\|u_{1}-u_{2}\right\|_{q}\right) \tag{9}
\end{equation*}
$$

for all $\left(t_{i}, s_{i}, u_{i}\right) \in W, i=1,2$.
Then the Cauchy problem (1)-(2) has a unique local solution $u \in C([0, a): X) \cap C^{1}((0, a): X)$.
Proof: Choose $t^{*}>0$ and $\delta>0$ such that estimates (7) - (9) hold on the sets

$$
\begin{gathered}
V=\left\{(t, u): 0 \leq t \leq t^{*},\left\|u-u_{0}\right\| \leq \delta\right\} \\
U=\left\{(t, s, u, v): 0 \leq t, s \leq t^{*},\left\|u-u_{0}\right\| \leq \delta,\left\|v-v_{0}\right\| \leq \delta\right\},
\end{gathered}
$$

and $W=\left\{(t, s, u): 0 \leq t, s \leq t^{*},\left\|u-u_{0}\right\| \leq \delta\right\}$, respectively.
Let

$$
B=\max _{0 \leq t<a}\left\|f\left(t, u_{0}\right)\right\|
$$

and

$$
H=\max _{0 \leq t, s \leq t^{*}}\left\|h\left(t, s, u_{0}, \int_{0}^{s} k\left(s, \tau, u_{0}\right) d \tau\right)\right\|
$$

and choose $a$ such that for $0 \leq t<a$,

$$
\begin{equation*}
\left\|Q\left(t^{\alpha} \theta\right)-I\right\|\left\|A^{q} u_{0}\right\| \leq \frac{\delta}{2} \tag{10}
\end{equation*}
$$

and

$$
\begin{equation*}
0<a<\min \left\{t^{*},\left[\frac{\delta}{2} M_{q}^{-1}(1-q)\left(L \delta+B+L_{1} \delta a+L_{1} L_{2} \delta a^{2}+H a\right)^{-1}\right]^{\frac{1}{\alpha(1-q)}}\right\} \tag{11}
\end{equation*}
$$

Let $Y$ be a Banach space $C((0, a]: X)$ with usual supremum norm which we denote by $\|\cdot\|_{Y}$. Define a map $F: Y \rightarrow Y$ by

$$
\begin{align*}
& F y(t)=\int_{0}^{\infty} \zeta_{\alpha}(\theta) Q\left(t^{\alpha} \theta\right) A^{q} u_{0} d \theta \\
&+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta) A^{q} Q\left((t-s)^{\alpha} \theta\right)\left[f\left(s, A^{-q} y(s)\right)\right. \\
&\left.+\int_{0}^{s} h\left(s, \tau, A^{-q} y(\tau), \int_{0}^{\tau} k\left(\tau, \mu, A^{-q} y(\mu)\right) d \mu\right) d \tau\right] d \theta d s \tag{12}
\end{align*}
$$

Since $\int_{0}^{\infty} \zeta_{\alpha}(\theta) d \theta=1$, for every $y \in Y, F Y(0)=A^{q} u_{0}$, Let $S$ be the nonempty closed and bounded subset of $Y$ defined by

$$
S=\left\{y: y \in Y, y(0)=A^{q} u_{0},\left\|y(t)-A^{q} u_{0}\right\| \leq \delta\right\}
$$

For $y \in S$, we have

$$
\begin{gathered}
\left\|F y(t)-A^{q} u_{0}\right\| \leq\left\|Q\left(t^{\alpha} \theta\right)-I\right\|\left\|A^{q} u_{0}\right\|+ \\
+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta)\left\|A^{q} Q\left((t-s)^{\alpha} \theta\right)\right\|\left\|f\left(s, A^{-q} y(s)\right)-f\left(s, u_{0}\right)\right\| d \theta d s \\
+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta)\left\|A^{q} Q\left((t-s)^{\alpha} \theta\right)\right\|\left\|f\left(s, u_{0}\right)\right\| d \theta d s
\end{gathered}
$$

$$
\begin{gathered}
+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta)\left\|A^{q} Q\left((t-s)^{\alpha} \theta\right)\right\| \\
\left\|\left[\int_{0}^{s} h\left(s, \tau, A^{-q} y(\tau), \int_{0}^{\tau} k\left(\tau, \mu, A^{-q} y(\mu)\right) d \mu\right) d \tau-\int_{0}^{s} h\left(s, \tau, u_{0}, \int_{0}^{\tau} k\left(\tau, \mu, u_{0}\right) d \mu\right) d \tau\right]\right\| d \theta d s \\
+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta)\left\|A^{q} Q\left((t-s)^{\alpha} \theta\right)\right\|\left\|\int_{0}^{s} h\left(s, \tau, u_{0}, \int_{0}^{\tau} k\left(\tau, \mu, u_{0}\right) d \mu\right) d \tau\right\| d \theta d s
\end{gathered}
$$

Since $\int_{0}^{\infty} \theta^{1-q} \zeta_{\alpha}(\theta) d \theta \leq 1$, so by using Lemma 1 (c), equations (10) and (11), above inequality gives

$$
\left\|F y(t)-A^{q} u_{0}\right\| \leq \frac{\delta}{2}+M_{q}(1-q)^{-1}\left\{L \delta+B+L_{1} \delta a+L_{1} L_{2} \delta a^{2}+H a\right\} a^{\alpha(1-q)} \leq \delta
$$

Therefore, $F$ maps $S$ into itself. Moreover, if $y_{1}, y_{2} \in S$, then

$$
\begin{gathered}
\left\|F y_{1}(t)-F y_{2}(t)\right\| \leq \alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta)\left\|A^{q} Q\left((t-s)^{\alpha} \theta\right)\right\| \\
\left\|f\left(s, A^{-q} y_{1}(s)\right)-f\left(s, A^{-q} y_{2}(s)\right)\right\| d \theta d s+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta)\left\|A^{q} Q\left((t-s)^{\alpha} \theta\right)\right\| \\
\|\left[\int_{0}^{s} h\left(s, \tau, A^{-q} y_{1}(\tau), \int_{0}^{\tau} k\left(\tau, \mu, A^{-q} y_{1}(\mu)\right) d \mu\right)\right. \\
\left.\quad-\int_{0}^{s} h\left(s, \tau, A^{-q} y_{2}(\tau), \int_{0}^{\tau} k\left(\tau, \mu, A^{-q} y_{2}(\mu)\right) d \mu\right) d \tau\right] \| d \theta d s \\
\leq M_{q} a^{\alpha(1-q)}(1-q)^{-1} L\left\|y_{1}-y_{2}\right\|_{Y}+M_{q} a^{\alpha(1-q)}(1-q)^{-1} L_{1}\left[\left(\left\|y_{1}-y_{2}\right\|_{Y}+L_{2}\left\|y_{1}-y_{2}\right\|_{Y} a\right) a\right] \\
\leq M_{q} a^{\alpha(1-q)}(1-q)^{-1}\left[L+L_{1}\left(1+L_{2} a\right) a\right]\left\|y_{1}-y_{2}\right\|_{Y} \\
\leq \frac{1}{2}\left\|y_{1}-y_{2}\right\|_{Y},
\end{gathered}
$$

which implies that

$$
\left\|F y_{1}-F y_{2}\right\|_{Y} \leq \frac{1}{2}\left\|y_{1}-y_{2}\right\|_{Y}
$$

By the contraction mapping theorem, mapping $F$ has a unique fixed point $y \in S$. This fixed point satisfies the integral equation

$$
\begin{gather*}
y(t)=\int_{0}^{\infty} \zeta_{\alpha}(\theta) Q\left(t^{\alpha} \theta\right) A^{q} u_{0} d \theta+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta) A^{q} Q\left((t-s)^{\alpha} \theta\right) \\
{\left[f\left(s, A^{-q} y(s)\right)+\int_{0}^{s} h\left(s, \tau, A^{-q} y(\tau), \int_{0}^{\tau} k\left(\tau, \mu, A^{-q} y(\mu)\right) d \mu\right) d \tau\right] d \theta d s} \tag{13}
\end{gather*}
$$

From (7), (8) and the continuity of $y$ it follows that

$$
t \rightarrow f\left(t, A^{-q} y(t)\right)
$$

and

$$
t \rightarrow h\left(t, s, A^{-q} y(s), \int_{0}^{s} k\left(s, \tau, A^{-q} y(\tau)\right) d \tau\right)
$$

are continuous on $[0, a]$, and, hence, there exist constants $N_{1}$ and $N_{2}$ such that

$$
\begin{equation*}
\left\|f\left(t, A^{-q} y(t)\right)\right\| \leq N_{1} \tag{14}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\|h\left(t, s, A^{-q} y(s), \int_{0}^{s} k\left(s, \tau, A^{-q} y(\tau)\right) d \tau\right)\right\| \leq N_{2} \tag{15}
\end{equation*}
$$

By using the same method as in [15, Theorem 3.2], we can prove that $y(t)$ is locally Hölder continuous on $(0, a]$. Then there exist a constant $C$ such that for every $t^{\prime}>0$, we have

$$
\|y(t)-y(s)\| \leq C|t-s|^{\gamma}
$$

for all $0 \leq t^{\prime} \leq t, s \leq a$. The local Hölder continuity of $t \rightarrow f\left(t, A^{-q} y(t)\right)$ follows from

$$
\left\|f\left(t, A^{-q} y(t)\right)-f\left(s, A^{-q} y(s)\right)\right\| \leq L\left(|t-s|^{\vartheta}+\|y(t)-y(s)\|\right) \leq C_{1}\left(|t-s|^{\vartheta}+|t-s|^{\gamma}\right)
$$

for some $C_{1}>0$ and the local Hölder continuity of

$$
t \rightarrow h\left(t, s, A^{-q} y(s), \int_{0}^{s} k\left(s, \tau, A^{-q} y(\tau)\right) d \tau\right)
$$

follows from

$$
\begin{gathered}
\left\|h\left(t, s, A^{-q} y(s), \int_{0}^{s} k\left(s, \tau, A^{-q} y(\tau)\right) d \tau\right)-h\left(t, \mu, A^{-q} y(\mu), \int_{0}^{s} k\left(\mu, \phi, A^{-q} y(\phi)\right) d \phi\right)\right\| \\
\leq L_{1}\left\{|s-\mu|^{\vartheta}+\|y(s)-y(\mu)\|+L_{2}\left(|s-\mu|^{\vartheta}+|\tau-\phi|^{\vartheta}+\|y(\tau)-y(\phi)\|\right) a\right\} \\
\leq L_{1}\left\{|s-\mu|^{\vartheta}+|s-\mu|^{\gamma}+L_{3}\left(|s-\mu|^{\vartheta}+|\tau-\phi|^{\vartheta}+|\tau-\phi|^{\gamma}\right) a\right\}
\end{gathered}
$$

for some $L_{3}>0$. Let $y$ be a solution of (13). Consider the inhomogeneous initial value problem

$$
\begin{align*}
& \frac{d^{\alpha} u(t)}{d t^{\alpha}}+A u(t)=f\left(t, A^{-q} y(t)\right)+\int_{0}^{t} h\left(t, s, A^{-q} y(s), \int_{0}^{s} k\left(s, \tau, A^{-q} y(\tau)\right) d \tau\right) d s  \tag{16}\\
& u(0)=u_{0} . \tag{17}
\end{align*}
$$

This problem has a unique solution $u \in C^{1}((0, a]: X)$ [21], which is given by

$$
\begin{align*}
& u(t)=\int_{0}^{\infty} \zeta_{\alpha}(\theta) Q\left(t^{\alpha} \theta\right) u_{0} d \theta \\
&+\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta) Q\left((t-s)^{\alpha} \theta\right)\left[f\left(s, A^{-q} y(s)\right)\right. \\
&\left.+\int_{0}^{s} h\left(s, \tau, A^{-q} y(\tau), \int_{0}^{\tau} k\left(\tau, \mu, A^{-q} y(\mu)\right) d \mu\right) d \tau\right] d \theta d s \tag{18}
\end{align*}
$$

for $t>0$, each term of (18) belongs to $D(A)$ and a fortiori in $D\left(A^{q}\right)$. Operating on both sides of (18) with $A^{q}$ we find that

$$
\begin{align*}
A^{q} u(t)= & \int_{0}^{\infty} \zeta_{\alpha}(\theta) Q\left(t^{\alpha} \theta\right) A^{q} u_{0} d \theta \\
& +\alpha \int_{0}^{t} \int_{0}^{\infty} \theta(t-s)^{\alpha-1} \zeta_{\alpha}(\theta) A^{q} Q\left((t-s)^{\alpha} \theta\right)\left[f\left(s, A^{-q} y(s)\right)\right. \\
& \left.+\int_{0}^{s} h\left(s, \tau, A^{-q} y(\tau), \int_{0}^{\tau} k\left(\tau, \mu, A^{-q} y(\mu)\right) d \mu\right) d \tau\right] d \theta d s \tag{19}
\end{align*}
$$

From (13) the right hand side of (19) equals $\boldsymbol{y}(\boldsymbol{t})$ and therefore $\boldsymbol{u}(\boldsymbol{t})=\boldsymbol{A}^{-\boldsymbol{q}} \boldsymbol{y}(\boldsymbol{t})$ and by (18), $\boldsymbol{u}$ is a $\boldsymbol{C}^{\mathbf{1}}((\mathbf{0}, a]: \boldsymbol{X})$ solution of (1)-(2). The uniqueness of $\boldsymbol{u}$ follows from the uniqueness of the solutions of (13) and (16) - (17). Hence, the theorem is proved.
