#### Abstract

This paper is concerned with Osculator interpolation polynomial to solve multi parameter eigenvalue problems for ordinary differential equations. The method finds the multi - parameter eigenvalues and the corresponding nonzero eigenvector can be decoupled using new technique which represent the solution of the problem in a certain domain. Illustration examples is presented, which confirm the theoretical predictions with a comparison between suggested technique and other methods.

Keywords: Ordinary differential equation, Eigenvalue, Eigenvector, Interpolation polynomial, multi-parameter eigenvalue problems.

## 1. Introduction

The present paper is concerned with a repeated interpolation polynomial to solve multi parameter eigenvalue problems using osculator interpolation polynomial. The problem involves finding an eigenvalue $\lambda$ and the corresponding nonzero eigenvector that satisfy the solution of the problem.

The eigenvalue problems can be used in a variety of problems in science and engineering. For example, in oscillation analysis with damping [1-3] and stability problems in fluid dynamics [4], and the three-dimensional (3D) Schrödinger equation can result in a cubic eigenvalue problem [5].

Many methods are used to solve multi - parameter eigenvalue problems (MPEP). Polynomial eigenvalue problems are typically solved by linearization [6], [7], which promotes the $k$-th order $\mathrm{n} \times \mathrm{n}$ matrix polynomial into the larger $\mathrm{kn} \times \mathrm{kn}$ linear eigenvalue problem. Other methods, such as Arnoldi shift and invert strategy [8], can be used when several eigenvalues are desired. A disadvantage of the shift-and-invert Arnoldi methods is that a change of the shift parameter requires a new Krylov subspace to be built. Another approach is a direct solution obtained by means of the Jacobi-Davidson method [9], although this method has been investigated far less extensively.

In the present paper, we propose a series solution of multi - parameter eigenvalue problems by means of the osculator interpolation polynomial. The proposed method enables us to obtain the eigenvalues and the corresponding nonzero eigenvector of the 2 nd order BVP.

The remainder of the paper is organized as follows. In the next section, we introduce the osculator interpolation polynomial. In section 3, we present the suggested technique. Illustration example is shown in Section 4. Finally, conclusions are presented in Section 5.

## 2. Osculator Interpolation Polynomial

In this paper we use two-point osculatory interpolation polynomial, essentially this is a generalization of interpolation using Taylor polynomials. The idea is to approximate a function y by a polynomial $P$ in which values of $y$ and any number of its derivatives at a given points are fitted by the corresponding function values and derivatives of P [10].

We are particularly concerned with fitting function values and derivatives at the two end points of a finite interval, say $[0,1]$, i.e., $P^{(j)}\left(\mathrm{x}_{\mathrm{i}}\right)=\mathrm{f}^{(\mathrm{j})}\left(\mathrm{x}_{\mathrm{i}}\right), \mathrm{j}=0, \ldots, \mathrm{n}, \mathrm{x}_{\mathrm{i}}=0,1$, where a useful and succinct way of writing osculatory interpolant $P_{2 n+1}$ of degree $2 n+1$ was given for example by Phillips [11] as:

$$
\begin{align*}
& \mathrm{P}_{2 \mathrm{n}+1}(\mathrm{x})=\sum_{j=0}^{n}\left\{\mathrm{y}^{(j)}(0) \mathrm{q}_{j}(\mathrm{x})+(-1)^{j} \mathrm{y}^{(j)}(1) \mathrm{q}_{j}(1-\mathrm{x})\right\},  \tag{1}\\
& \mathrm{q}_{j}(\mathrm{x})=\left(\mathrm{x}^{j} / \mathrm{j}!\right)(1-\mathrm{x})^{n+1} \sum_{s=0}^{n-j}\binom{n+s}{s} \mathrm{x}^{\mathrm{s}}=\mathrm{Q}_{j}(\mathrm{x}) / \mathrm{j}! \tag{2}
\end{align*}
$$

so that (1) with (2) satisfies:

$$
\mathrm{y}^{(j)}(0)=P_{2 n+1}^{(j)}(0), \quad \mathrm{y}^{(j)}(1)=P_{2 n+1}^{(j)}(1), \quad \mathrm{j}=0,1,2, \ldots, \mathrm{n} .
$$

implying that $\mathrm{P}_{2 \mathrm{n}+1}$ agrees with the appropriately truncated Taylor series for y about $\mathrm{x}=0$ and $\mathrm{x}=1$. We observe that (1) can be written directly in terms of the Taylor coefficients $a_{i}$ and $b_{i}$ about $\mathrm{x}=0$ and $x=1$ respectively, as:

$$
\begin{equation*}
\mathrm{P}_{2 \mathrm{n}+1}(\mathrm{x})=\sum_{j=0}^{n}\left\{a_{j} \mathrm{Q}_{j}(\mathrm{x})+(-1)^{j} b_{j} \mathrm{Q}_{j}(1-\mathrm{x})\right\} \tag{3}
\end{equation*}
$$

## 3. Solution of the Multi - Parameter Eigenvalue Problems

In this section, we suggest a repeated interpolation technique which is based on osculatory interpolating polynomials $\mathrm{P}_{2 \mathrm{n}+1}$ and Taylor series expansion to solve $2^{\text {nd }}$ order multi-parameter eigenvalue problems. A general form of $2^{\text {nd }}$ order MPEVP is:

$$
\begin{equation*}
y^{\prime \prime}(x)=f\left(x, y, y^{\prime}, \lambda_{i}\right), \quad i=1, \ldots, n, n \in I^{+}, \quad 0 \leq x \leq 1, \tag{4a}
\end{equation*}
$$

Subject to the boundary condition (BC):
In the case Dirichlet $B C: y(0)=A, y(1)=B$, where $A, B \in R$
In the case Neumann $B C$ : $y^{\prime}(0)=A, y^{\prime}(1)=B$, where $A, B \in R$
In the case Cauchy or mixed $B C$ : $y(0)=A, y^{\prime}(1)=B$, where $A, B \in R$
Or

$$
\begin{equation*}
\mathrm{y}^{\prime}(0)=\mathrm{A}, \mathrm{y}(1)=\mathrm{B}, \text { where } \mathrm{A}, \mathrm{~B} \in \mathrm{R} \tag{4d}
\end{equation*}
$$

where $f$, in general, nonlinear function of their arguments.
Now, to solve the problem by the suggested method doing the following steps:

## Step one

Evaluate Taylor series of $y(x)$ about $x=0$ :

$$
\begin{equation*}
\mathrm{y}=\sum_{i=0}^{\infty} a_{i} x^{i}=\mathrm{a}_{0}+\mathrm{a}_{1} \mathrm{x}+\sum_{i=2}^{\infty} \mathrm{a}_{i} \mathrm{x}^{i} \tag{5}
\end{equation*}
$$

where $y(0)=a_{0}, y^{\prime}(0)=a_{1}, y^{\prime \prime}(0) / 2!=a_{2}, \ldots, y^{(i)}(0) / i!=a_{i}, i=3,4, \ldots$
And evaluate Taylor series of $y(x)$ about $x=1$ :

$$
\begin{equation*}
\mathrm{y}=\sum_{i=0}^{\infty} b_{i}(x-1)^{i}=\mathrm{b}_{0}+\mathrm{b}_{1}(\mathrm{x}-1)+\sum_{i=2}^{\infty} \mathrm{b}_{i}(\mathrm{x}-1)^{i} \tag{6}
\end{equation*}
$$

where $y(1)=b_{0}, y^{\prime}(1)=b_{1}, y^{\prime \prime}(1) / 2!=b_{2}, \ldots, y^{(i)}(1) / i!=b_{i}, i=3,4, \ldots$

## Step two

Insert the series form (5) into equation (4a) and put $x=0$, then equate the coefficients of powers of x to obtain $\mathrm{a}_{2}$.

Insert the series form (6) into equation (4a) and put $\mathrm{x}=1$, then equate the coefficients of powers of ( $\mathrm{x}-1$ ) to obtain $\mathrm{b}_{2}$.

## Step three

Derive equation (4a) with respect to $x$, to get new form of the equation say (7) as follows:

$$
\begin{equation*}
y^{\prime \prime \prime}(x)=\frac{d f\left(x, y, y^{\prime}, \lambda_{i}\right)}{d x} \tag{7}
\end{equation*}
$$

then, insert the series form (5) into equation (7) and put $\mathrm{x}=0$ and equate the coefficients of powers of x to obtain $a_{3}$, again insert the series form (6) into equation (7) and put $x=1$, then equate the coefficients of powers of ( $\mathrm{x}-1$ ) to obtain $\mathrm{b}_{3}$.

## Step four

Iterate the above process many times to obtain $a_{4}, b_{4}$ then $a_{5}, b_{5}$ and so on, that is, to get $a_{i} a_{i} b_{i}$ for all $i \geq 2$, the resulting equations can be solved using MATLAB version 7.12 , to obtain $a_{i}$ and $b_{i}$ for all $\mathrm{i} \geq 2$.

## Step five

The notation implies that the coefficients depend only on the indicated unknowns $a_{0}, a_{1}, b_{0}, b_{1}$, and $\lambda_{\mathrm{i}}, \mathrm{i}=1, \ldots, \mathrm{n}, \mathrm{n} \in \mathrm{I}^{+}$, use the BC to get two coefficients from these unknown coefficients.

Now, we can construct two point osculatory interpolating polynomial $\mathrm{P}_{2 \mathrm{n}+1}(\mathrm{x})$ by insert these coefficients ( $\mathrm{a}_{\mathrm{i}} \mathrm{S}_{\mathrm{S}}$ and $\mathrm{b}_{\mathrm{i}}{ }^{\mathbf{S}}$ ) into equation (3).

## Step six

To find the unknowns coefficients integrate equation (4a) on $[0, x]$ to obtain:

$$
\begin{equation*}
y^{\prime}(x)-y^{\prime}(0)-\int_{0}^{x} f\left(s, y, y^{\prime}, \lambda_{i}\right) d s=0 \tag{8a}
\end{equation*}
$$

and again integrate equation (8a) on $[0, x]$ to obtain:

$$
\begin{equation*}
y(x)-y(0)-y^{\prime}(0) x-\int_{0}^{x}(1-s) f\left(s, y, y^{\prime}, \lambda_{i}\right) d s=0 \tag{8b}
\end{equation*}
$$

## Step seven

Putting $x=1$ in equations (8) to get:

$$
\begin{equation*}
\mathrm{b}_{1}-\mathrm{a}_{1}-\int_{0}^{1} \mathrm{f}\left(\mathrm{~s}, \mathrm{y}, \mathrm{y}^{\prime}, \lambda_{\mathrm{i}}\right) \mathrm{ds}=0 \tag{9a}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{b}_{0}-\mathrm{a}_{0}-\mathrm{a}_{1}-\int_{0}^{1}(1-\mathrm{s}) \mathrm{f}\left(\mathrm{~s}, \mathrm{y}, \mathrm{y}^{\prime}, \lambda_{\mathrm{i}}\right) \mathrm{ds}=0 \tag{9b}
\end{equation*}
$$

## Step eight

Use $P_{2 n+1}(x)$ which constructed in step five as a replacement of $y(x)$, we see that equations (9) have only two unknown coefficients from $\mathrm{a}_{0}, \mathrm{a}_{1}, \mathrm{~b}_{0}, \mathrm{~b}_{1}$ and $\lambda_{\mathrm{i}}$. If the BC is Dirichlet, that is, we have $\mathrm{a}_{0}$ and $b_{0}$, then equations (9) have two unknown coefficients $a_{1}, b_{1}$ and $\lambda_{i}$. If the BC is Neumann, that is, we have $a_{1}$ and $b_{1}$, then equations (9) have two unknown coefficients $a_{0}, b_{0}$ and $\lambda_{i}$. Finally, if the BC is mixed condition, i.e., we have $a_{0}$ and $b_{1}$ or $a_{1}$ and $b_{0}$, then equations (9) have two unknown coefficients $a_{1}, b_{0}$ or $a_{0}, b_{1}$ and $\lambda_{i}$.

## Step nine

$$
\text { If } \mathrm{n}=3 \text {, then }
$$

In the case of Dirichlet BC, we have:

$$
\begin{align*}
& F\left(a_{1}, b_{1}, \lambda_{i}\right)=b_{1}-a_{1}-\int_{0}^{1} f\left(s, y, y^{\prime}, \lambda_{i}\right) d s=0  \tag{10a}\\
& G\left(a_{1}, b_{1}, \lambda_{i}\right)=b_{0}-a_{0}-a_{1}-\int_{0}^{1}(1-s) f\left(s, y, y^{\prime}, \lambda_{i}\right) d s=0  \tag{10b}\\
& \left(\partial F / \partial a_{1}\right)-\left(\partial G / \partial a_{1}\right)=0  \tag{10c}\\
& \left(\partial F / \partial b_{1}\right)-\left(\partial G / \partial b_{1}\right)=0  \tag{10d}\\
& \left(\partial F / \partial a_{1}\right)\left(\partial G / \partial b_{1}\right)-\left(\partial F / \partial b_{1}\right)\left(\partial G / \partial a_{1}\right)=0 \tag{10e}
\end{align*}
$$

In the case of Neumann BC, we have:

$$
\begin{equation*}
\mathrm{F}\left(\mathrm{a}_{0}, \mathrm{~b}_{0}, \lambda_{\mathrm{i}}\right)=\mathrm{b}_{1}-\mathrm{a}_{1}-\int_{0}^{1} \mathrm{f}\left(\mathrm{~s}, \mathrm{y}, \mathrm{y}^{\prime}, \lambda_{\mathrm{i}}\right) \mathrm{ds}=0 \tag{11a}
\end{equation*}
$$

$\mathrm{G}\left(\mathrm{a}_{0}, \mathrm{~b}_{0}, \lambda_{\mathrm{i}}\right)=\mathrm{b}_{0}-\mathrm{a}_{0}-\mathrm{a}_{1}-\int_{0}^{1}(1-\mathrm{s}) \mathrm{f}\left(\mathrm{s}, \mathrm{y}, \mathrm{y}^{\prime}, \lambda_{\mathrm{i}}\right) \mathrm{ds}=0$

$$
\begin{equation*}
\left(\partial \mathrm{F} / \partial \mathrm{a}_{0}\right)-\left(\partial \mathrm{G} / \partial \mathrm{a}_{0}\right)=0 \tag{11c}
\end{equation*}
$$

$$
\begin{equation*}
\left(\partial \mathrm{F} / \partial \mathrm{b}_{0}\right)-\left(\partial \mathrm{G} / \partial \mathrm{b}_{0}\right)=0 \tag{11d}
\end{equation*}
$$

$\left(\partial \mathrm{F} / \partial \mathrm{a}_{0}\right)\left(\partial \mathrm{G} / \partial \mathrm{b}_{0}\right)-\left(\partial \mathrm{F} / \partial \mathrm{b}_{0}\right)\left(\partial \mathrm{G} / \partial \mathrm{a}_{0}\right)=0$
In the case of mixed BC, we have:

$$
\begin{equation*}
\mathrm{F}\left(\mathrm{a}_{1}, \mathrm{~b}_{0}, \lambda_{\mathrm{i}}\right)=\mathrm{b}_{1}-\mathrm{a}_{1}-\int_{0}^{1} \mathrm{f}\left(\mathrm{~s}, \mathrm{y}, \mathrm{y}^{\prime}, \lambda_{\mathrm{i}}\right) \mathrm{ds}=0 \tag{12a}
\end{equation*}
$$

$G\left(a_{1}, b_{0}, \lambda_{i}\right)=b_{0}-a_{0}-a_{1}-\int_{0}^{1}(1-s) f\left(s, y, y^{\prime}, \lambda_{i}\right) d s=0$
$\left(\partial \mathrm{F} / \partial \mathrm{a}_{1}\right)-\left(\partial \mathrm{G} / \partial \mathrm{a}_{1}\right)=0$
$\left(\partial \mathrm{F} / \partial \mathrm{b}_{0}\right)-\left(\partial \mathrm{G} / \partial \mathrm{b}_{0}\right)=0$
$\left(\partial \mathrm{F} / \partial \mathrm{a}_{1}\right)\left(\partial \mathrm{G} / \partial \mathrm{b}_{0}\right)-\left(\partial \mathrm{F} / \partial \mathrm{b}_{0}\right)\left(\partial \mathrm{G} / \partial \mathrm{a}_{1}\right)=0$
Or

$$
\begin{align*}
& F\left(a_{0}, b_{1}, \lambda_{i}\right)=b_{1}-a_{1}-\int_{0}^{1} f\left(s, y, y^{\prime}, \lambda_{i}\right) d s=0  \tag{13a}\\
& G\left(a_{0}, b_{1}, \lambda_{i}\right)=b_{0}-a_{0}-a_{1}-\int_{0}^{1}(1-s) f\left(s, y, y^{\prime}, \lambda_{i}\right) d s=0 \tag{13b}
\end{align*}
$$

$$
\begin{equation*}
\left(\partial \mathrm{F} / \partial \mathrm{a}_{0}\right)-\left(\partial \mathrm{G} / \partial \mathrm{a}_{0}\right)=0 \tag{13c}
\end{equation*}
$$

```
\(\left(\partial \mathrm{F} / \partial \mathrm{b}_{1}\right)-\left(\partial \mathrm{G} / \partial \mathrm{b}_{1}\right)=0\)
\(\left(\partial \mathrm{F} / \partial \mathrm{a}_{0}\right)\left(\partial \mathrm{G} / \partial \mathrm{b}_{1}\right)-\left(\partial \mathrm{F} / \partial \mathrm{b}_{1}\right)\left(\partial \mathrm{G} / \partial \mathrm{a}_{0}\right)=0\)
```

So, we can find the unknown coefficients by solving the system of algebraic equations: (10) or (11) or (12) or (13) using MATLAB, so insert the value of the unknown coefficients into equation (3), thus equation (3) represent the solution of the problem.

## 4. Example

In this section, we illustrate suggested method using example of multi-parameter eigenvalue problems. The algorithm was implemented in MATLAB version 7.12.

The bvp4c solver of MATLAB has been modified accordingly so that it can solve some class of multi-parameter eigenvalue problems as effectively as it previously solved eigenvalue problems.

The following problem arises in a study of heat and mass transfer in a porous spherical catalyst with a first order reaction. There is a singular coefficient arising from the reduction of a partial differential equation to an ODE by symmetry [12]. The MPEVP is:

$$
y^{\prime \prime}+\frac{2}{x} y^{\prime}=\lambda_{1}^{2} y e^{\frac{\lambda_{2} \lambda_{3}(1-y)}{1+\lambda_{3}(1-y)}}, \quad \mathrm{x} \in[0,1]
$$

The BC (mixed case) are $y(1)=1$ and the symmetry condition $y^{\prime}(0)=0$. Now, we solve this problem by suggested method. Here equations (13) become:

$$
\begin{align*}
& \mathrm{F}\left(\mathrm{a}_{0}, \mathrm{~b}_{1}, \lambda_{1}, \lambda_{2}, \lambda_{3}\right)=\mathrm{b}_{1}-1+\lambda_{1} \int_{0}^{1} \mathrm{~s} y e^{\frac{\lambda_{2} \lambda_{3}(1-y)}{1+\lambda_{3}(1-y)}} \mathrm{ds}=0,  \tag{13a}\\
& \mathrm{G}\left(\mathrm{a}_{0}, \mathrm{~b}_{1}, \lambda_{1}, \lambda_{2}, \lambda_{3}\right)=1-2 \int_{0}^{1} \mathrm{y}(\mathrm{~s}) \mathrm{ds}+\lambda^{2} \int_{0}^{1} \mathrm{~s}(1-\mathrm{s}) y e^{\frac{\lambda_{2} \lambda_{3}(1-y)}{1+\lambda_{3}(1-y)}} \mathrm{ds}=0,  \tag{13a}\\
& \left(\partial \mathrm{~F} / \partial \mathrm{a}_{0}\right)-\left(\partial \mathrm{G} / \partial \mathrm{a}_{0}\right)=0  \tag{13c}\\
& \left(\partial \mathrm{~F} / \partial \mathrm{b}_{1}\right)-\left(\partial \mathrm{G} / \partial \mathrm{b}_{1}\right)=0  \tag{13d}\\
& \left(\partial \mathrm{~F} / \partial \mathrm{a}_{0}\right)\left(\partial \mathrm{G} / \partial \mathrm{b}_{1}\right)-\left(\partial \mathrm{F} / \partial \mathrm{b}_{1}\right)\left(\partial \mathrm{G} / \partial \mathrm{a}_{0}\right)=0 \tag{13e}
\end{align*}
$$

Now, we have to solve equations (13) for the unknowns $a_{0}, b_{1}, \lambda_{1}, \lambda_{2}, \lambda_{3}$ using MATLAB, then we have $\mathrm{a}_{0}=0.64, \mathrm{~b}_{1}=0, \lambda_{1}=0.6, \lambda_{2}=40$ and $\lambda_{3}=0.2$. Then from equation (3) we have (where $n=4$ ):
$P_{9}=18.63018391074087 x^{9}-81.86548669822514 x^{8}+136.0606573968419 x^{7}-101.7163034006953 x^{6}+$ $29.5919367027597 x^{5}-1.076125341642182 x^{4}+0.7351374287263839 x^{2}+0.64$.

Higher accuracy can be obtained by evaluating higher $n$, now take $n=10$, we have:
$\mathrm{P}_{21}=52535.82045238554 \mathrm{x}^{21}-549779.0547394637 \mathrm{x}^{20}+2594544.959251828 \mathrm{x}^{19}-7272910.909707223 \mathrm{x}^{18}+$ $13413618.49119748 x^{17}-17012485.96003969 x^{16}+15031675.07293067 x^{15}-9139740.80568491 x^{14}+$ $3661565.477401016 x^{13}-73218.8815826758 x^{12}+94190.70616882079 x^{11}+7.614357331206804 x^{10}-$ $3.760089006497641 x^{8}+1.931071345092823 x^{6}-1.076125341636627 x^{4}+0.7351374287263839 x^{2}+0.64$

If we take $\mathrm{n}=11$, we have:
$P_{23}=2307273.5847575 x^{22}-201189.35259898 x^{23}-12048976.340348 x^{21}+37826952.9633766 x^{20}-$ $79339407.916265 x^{19}+116759503.0267302 x^{18}-123051968.6595243 x^{17}+92896106.64761737 x^{16}-$ $49247501.14161112 x^{15}+17467140.105114 x^{14}-3732006.240472856 x^{13}+364068.2388733 x^{12}+$ $7.614357331206804 x^{10}-3.7600890064976 x^{8}+1.9310713450928 x^{6}-0.0761253416366 x^{4}+$ $0.735137428726 x^{2}+0.64$.

Table (1), gave a comparison between $\mathrm{P}_{21}$ and $\mathrm{P}_{23}$ at the ten equidistance point in the domain. Kubiček et al (see [12], [13]) solved this problem by the collection method and got three solutions assembled by consider a range of parameter values: $\lambda_{1}, \lambda_{2}, \lambda_{3}$ such that, the values $\lambda_{1}=0.6, \lambda_{2}=0.1, \lambda_{3}$ $=0.2$, used in ex6bvp.m lead to three solutions that are displayed in Figure (1).

| 1 | $\mathbf{0 . 9 9 9 9 9 9 9 9 4 5 1 9 2 0 9}$ | $\mathbf{0 . 9 9 9 9 9 9 9 6 0 3 5 1 3 1 2}$ | $\mathbf{0 . 0 0 0 0 0 0 0 0 3 4 1 6 7 8 9 7}$ |

Figure 1: Multiple solutions of example, gave in [12]

Another solution of this problem gave in [14] using collocation method with different code in MATLAB and FORTRAN given in Table (2) and Figure (2).

Table 2: Comparisons for different code of solution in [14] with TOL $=10^{-7}$

|  | bvp4c | CW-4 | CW-6 | sbvp4 | sbvp4g | sbvp6 | sbvp6g |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| N | 205 | 41 | 21 | 57 | 57 | 22 | 15 |
| $\mathrm{f}_{\text {count }}$ | 6856 | 1080 | 840 | 6051 | 3699 | 3741 | 1431 |

Where:

- bvp4c (MATLAB 6.0 routine): which is based on collocation at three Lobatto points (see [14]). This is a method of order 4 for regular problems.
- COLNEW (Fortran 90 code): The basic method here is collocation at Gaussian points, we chose the polynomial degrees $m=4$ (CW-4) and $m=6$ (CW-6), which results in (super convergent) methods of orders 8 and 12 respectively (for regular problems).
- sbvp is used with equidistant (sbvp4 and sbvp6) and Gaussian (sbvp4g and sbvp6g) collocation points and polynomials of degrees 4 and 6 respectively.

Although for reasons mentioned here, the comparison of all three codes is difficult. Table (2) show the number of mesh points ( $N$ ) and the number of function evaluations (fcount) that the different solvers required to reach tolerance (TOL).

Figure 2: Solution of example gave in [14]

## 5. Conclusions

In the present paper, we have proposed osculator interpolation method to solve multi-point eigenvalue problems. It may be concluded that the suggested technique is a very powerful, efficient and can be used successfully for finding the solution of nonlinear multi-point eigenvalue problems with boundary condition.

The bvp4c solver of MATLAB has been modified accordingly so that it can solve some class of multi-point eigenvalue problems as effectively as it previously solved BVP.
